

AMENDMENTS TO THE CLAIMS

This listing of claims will replace all prior versions, and listings, of claims in the application:

Listing of Claims:

1. (Cancelled)
2. (Cancelled)
3. (Currently Amended) A reactance adjuster ~~as recited in claim 2, wherein said integrator comprises:~~ for adjusting reactance caused by a communication apparatus that transmits and/or receives a signal via an electric field transmittable medium, said reactance adjuster comprising:
 - a signal generation section generating a probe signal,
 - an electrode inducing an electric field based on said probe signal in said electric field transmittable medium,
 - a resonance section that is connected between said signal generation section and said electrode and induces a series resonance by adjusting reactance against parasitic capacitance induced between said electric field transmittable medium, said communication apparatus, and an earth ground,
 - an adjusting signal generation section outputting alternately a high level signal and a low level signal to said resonator section,
 - an electric field detection section that receives an electric field in said electric field transmittable medium and generates an electric signal based on the received electric field,
 - a signal output section including a first electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a high level signal to said resonator section, a second electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a low level signal to said resonator section, and a voltage comparator comparing a voltage across said first electric charge storing means and a voltage

across said second electric charge storing means to output a predetermined signal in accordance with the comparison result, and

a control section that outputs a voltage having a constant voltage value to said resonator section while either one of said first and said second electric charge storing means is storing an electric charge, and inputs said predetermined signal to output a voltage based on the inputted predetermined signal to said resonator section while said first and second electric charge storing means stop storing an electric charge,

wherein said control section comprises:

a constant voltage source outputting the voltage having a predetermined voltage value,

an integrator outputting a voltage having said constant voltage value when receiving the voltage having said predetermined voltage value and outputting a voltage based on said predetermined signal when receiving said predetermined voltage to said resonator section,

an output switching section inputting selectively the voltage having said predetermined voltage value or said predetermined signal, thus outputting said voltage having said predetermined voltage value to said integrator while either one of said first and said second electric charge storing means is storing an electric charge and outputting said predetermined signal to said integrator when said first and second electric charge storing means stop storing an electric charge. And

wherein said integrator comprises:

a first connection means, one end of which is connected to a positive electrode of a voltage source outputting a predetermined voltage,

a second connection means, one end of which is connected to the other end of said first connection means and the other end of which is connected to a negative electrode of said voltage source,

a first comparison means comparing a predetermined first threshold voltage and said predetermined signal to output a signal for turning on said first connection means when said predetermined signal is lower than said first threshold voltage,

a second comparison means comparing a second threshold voltage higher than said

first threshold voltage and said predetermined signal to output a signal for turning on said connection means when said predetermined signal is higher than said second threshold voltage, and

a capacitor, one end of which is connected to said other end of said first connection means and the other end of which is connected to said negative electrode.

4. (Previously Presented) A reactance adjuster as recited in claim 3, wherein said integrator further comprises:

a first current source provided between said positive electrode and said first connection means,

a third comparison means that compares said predetermined signal and a third threshold voltage lower than said first threshold voltage and outputs a current control signal to said first current source so that a first constant current having a predetermined current value flows from said first current source when said predetermined signal is lower than said threshold voltage or a second constant current smaller than said first constant current flows from said first current source when said predetermined signal is higher than said third threshold voltage and lower than said first threshold voltage,

a second current source provided between said negative electrode and said second connection means, and

a fourth comparison means that compares said predetermined signal and said fourth threshold voltage higher than said second threshold voltage and outputs a current control signal to said second current source so that a third constant current flows from said second current source when said predetermined signal is higher than said fourth threshold voltage or a fourth current smaller than said third current flows from said second current source when said predetermined signal is higher than said second threshold voltage and lower than said fourth threshold voltage.

5. (Previously Presented) A reactance adjuster as recited in claim 3, wherein said integrator further comprises:

a first variable current source provided between said positive electrode and said first connection means,

a first differential amplifying means that compares said predetermined signal and said first threshold voltage and outputs a current control signal to said first variable current source so that the smaller said determined signal is, the larger the current flows from said variable current source,

a second variable current source provided between said negative electrode and said second connection means, and

a second differential amplifying means that compares said predetermined signal and said second threshold voltage and outputs a current control signal to said second variable current source so that the higher said predetermined signal is, the larger the current flows from said second variable current source.

6. (Previously Presented) A reactance adjuster as recited in claim 3, wherein said integrator further comprises:

a first variable resistor provided between said positive electrode and said first connection means,

a first differential amplifying means that compares said predetermined signal and said first threshold voltage and outputs a resistance value control signal to said first variable resistor so that the lower said predetermined signal is, the lower the resistance of said first variable resistor becomes,

a second variable resistor provided between said negative electrode and said second connection means, and

a second differential amplifying means that compares said predetermined signal and said second threshold voltage and outputs a resistance value control signal to said second variable resistor so that the higher said predetermined signal is, the lower the resistance of said second variable resistor becomes.

7. (Currently Amended) A reactance adjuster ~~as recited in claim 1,~~ for adjusting reactance

caused by a communication apparatus that transmits and/or receives a signal via an electric field transmittable medium, said reactance adjustor comprising:

a signal generation section generating a probe signal,

an electrode inducing an electric field based on said probe signal in said electric field transmittable medium,

a resonance section that is connected between said signal generation section and said electrode and induces a series resonance by adjusting reactance against parasitic capacitance induced between said electric field transmittable medium, said communication apparatus, and an earth ground,

an adjusting signal generation section outputting alternately a high level signal and a low level signal to said resonator section,

an electric field detection section that receives an electric field in said electric field transmittable medium and generates an electric signal based on the received electric field,

a signal output section including a first electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a high level signal to said resonator section, a second electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a low level signal to said resonator section, and a voltage comparator comparing a voltage across said first electric charge storing means and a voltage across said second electric charge storing means to output a predetermined signal in accordance with the comparison result, and

a control section that outputs a voltage having a constant voltage value to said resonator section while either one of said first and said second electric charge storing means is storing an electric charge, and inputs said predetermined signal to output a voltage based on the inputted predetermined signal to said resonator section while said first and second electric charge storing means stop storing an electric charge,

wherein said control section comprises:

a first p-channel Metal Oxide Semiconductor Field Effect Transistor (MOS-FET) that turns off while either one of said first and said second electric charge storing means is storing

an electric charge and turns on when said first and said second electric charge storing means stop storing,

a second p-channel MOS-FET connected in series with said first p-channel MOS-FET, said second p-channel MOS-FET turning on when said voltage comparator determines that a voltage across said first electric charge storing means is higher than a voltage across said second electric charge storing means and turning off when said voltage comparator determines that a voltage across said first electric charge storing means is lower than a voltage across said second electric charge storing means,

a first n-channel MOS-FET connected in series with said second p-channel MOS-FET, said first n-channel MOS-FET turning on when said voltage comparator determines that a voltage across said first electric charge storing means is lower than a voltage across said second electric charge storing means and turning off when said voltage comparator determines that a voltage across said first electric charge storing means is higher than a voltage across said second electric charge storing means,

a second n-channel MOS-FET connected in series with said first n-channel MOS-FET, said second n-channel MOS-FET turning off when either one of said first and said second electric charge storing means is storing an electric charge and turning on when said first and said second electric charge storing means stop storing, and

a capacitor, one end of which is connected to a node between said second p-channel MOS-FET and said first n-channel MOS-FET and the other end of which is connected to the earth ground.

8. (Previously Presented) A reactance adjuster as recited in claim 7, wherein said control section further comprises:

a first reference voltage source outputs a predetermined first reference voltage,

a first voltage comparator comparing said predetermined signal and said first reference voltage to output a voltage in accordance with the comparison result to said second p-channel MOS-FET,

a second reference voltage source outputting a predetermined second reference voltage,

and

a second voltage comparator comparing said predetermined signal and said second reference voltage to output a voltage in accordance with the comparison result to said first n-channel MOS-FET.

9. (Previously Presented) A reactance adjuster as recited in claim 8, wherein said control section further comprises:

a first variable resistor connected between said first p-channel MOS-FET and said second p-channel MOS-FET,

a third comparator comparing said first reference voltage and said predetermined signal to output a signal in accordance with the comparison result so as to control resistance of said first variable resistor,

a second variable resistor connected between said first n-channel MOS-FET and said second n-channel MOS-FET, and

a fourth comparator comparing said second reference voltage and said predetermined signal to output a signal in accordance with the comparison result so as to control resistance of said second variable resistor.

10. (Previously Presented) A reactance adjuster as recited in claim 8, wherein said control section further comprises:

a first current source connected between said first p-channel MOS-FET and said second p-channel MOS-FET,

a third signal comparison means that compares said predetermined signal and a third reference voltage lower than said first reference voltage and outputs a current control signal to said first current source so that said first current source flows a first constant current when said predetermined signal is lower than said third reference voltage or said first current source flows a second constant current smaller than said first constant current when said predetermined signal is higher than said third reference voltage and lower than said first reference voltage,

a second current source connected between said first n-channel MOS-FET and said second n-channel MOS-FET, and

a fourth signal comparator that compares said predetermined signal and a fourth reference voltage higher than said second reference voltage and outputs a current control signal to said second current source so that said second current source flows a third constant current when said predetermined signal is higher than said fourth reference voltage or said second current source flows a fourth constant current smaller than said third constant current when said predetermined signal is higher than said second reference voltage and lower than said fourth reference voltage.

11. (Original) A reactance adjuster as recited in either claim 4 or 10, wherein said first constant current and said third constant current have a same current value, and wherein said second constant current and said fourth constant current have a same current value.

12. (Previously Presented) A reactance adjuster as recited in claim 8, wherein said control section further comprises:

a first variable current source connected between said first p-channel MOS-FET and said second p-channel MOS-FET,

a first differential amplifying means comparing said predetermined signal and said first reference voltage to output a current control signal to said first variable current source so that the smaller said predetermined signal is, the larger the current flows from said first variable current source,

a second variable current source connected between said first n-channel MOS-FET and said second n-channel MOS-FET, and

a second differential amplifying means comparing said predetermined signal and said second reference voltage to output a current control signal to said second variable current source so that the larger said predetermined signal is, the larger the current flows from said second variable current source.

13. (Cancelled)

14. (Currently Amended) A reactance adjuster as recited in claim 1, for adjusting reactance caused by a communication apparatus that transmits and/or receives a signal via an electric field transmittable medium, said reactance adjuster comprising:

a signal generation section generating a probe signal,

an electrode inducing an electric field based on said probe signal in said electric field transmittable medium,

a resonance section that is connected between said signal generation section and said electrode and induces a series resonance by adjusting reactance against parasitic capacitance induced between said electric field transmittable medium, said communication apparatus, and an earth ground,

an adjusting signal generation section outputting alternately a high level signal and a low level signal to said resonator section,

an electric field detection section that receives an electric field in said electric field transmittable medium and generates an electric signal based on the received electric field,

a signal output section including a first electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a high level signal to said resonator section, a second electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a low level signal to said resonator section, and a voltage comparator comparing a voltage across said first electric charge storing means and a voltage across said second electric charge storing means to output a predetermined signal in accordance with the comparison result, and

a control section that outputs a voltage having a constant voltage value to said resonator section while either one of said first and said second electric charge storing means is storing an electric charge, and inputs said predetermined signal to output a voltage based on the inputted predetermined signal to said resonator section while said first and second electric charge storing means stop storing an electric charge,

wherein said signal output section further comprises a sampling means sampling said electric signal to output a voltage in accordance with said electric signal.

15. (Currently Amended) A reactance adjuster ~~as recited in claim 1,~~ for adjusting reactance caused by a communication apparatus that transmits and/or receives a signal via an electric field transmittable medium, said reactance adjuster comprising:

a signal generation section generating a probe signal,

an electrode inducing an electric field based on said probe signal in said electric field transmittable medium,

a resonance section that is connected between said signal generation section and said electrode and induces a series resonance by adjusting reactance against parasitic capacitance induced between said electric field transmittable medium, said communication apparatus, and an earth ground,

an adjusting signal generation section outputting alternately a high level signal and a low level signal to said resonator section,

an electric field detection section that receives an electric field in said electric field transmittable medium and generates an electric signal based on the received electric field,

a signal output section including a first electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a high level signal to said resonator section, a second electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a low level signal to said resonator section, and a voltage comparator comparing a voltage across said first electric charge storing means and a voltage across said second electric charge storing means to output a predetermined signal in accordance with the comparison result, and

a control section that outputs a voltage having a constant voltage value to said resonator section while either one of said first and said second electric charge storing means is storing an electric charge, and inputs said predetermined signal to output a voltage based on the inputted predetermined signal to said resonator section while said first and second

electric charge storing means stop storing an electric charge.

wherein said signal output section further comprises a peak-hold means holding a peak value of an amplitude of said electric signal to output a voltage in accordance with the peak value.

16. (Previously Presented) A reactance adjuster as recited in claim 15, wherein said peak-hold means comprises an addition means detecting said peak value at a predetermined number of times to add said peak value.

17. (Cancelled)

18. (Canceled)

19. (Currently Amended) A signal processing circuit ~~as recited in claim 18~~, further comprising:

a first connection means, one end of which is connected to a positive electrode of a voltage source outputting a predetermined voltage,

a second connection means, one end of which is connected to the other end of said first connection means and the other end of which is connected to a negative electrode of said voltage source,

a first comparison means that compares a predetermined first threshold voltage and an input voltage and outputs a signal to turn on said first connection means when said input voltage is lower than said first threshold voltage,

a second comparison means that compares an input voltage and a second threshold voltage higher than said first threshold voltage and outputs a signal to turn on said second connection means when said input voltage is higher than said second threshold voltage,

a capacitor, one end of which is connected to said other end of said first connection means and the other end of which is connected to said negative electrodes,

a first current source provided between said positive electrode and said first

connection means,

a third comparison means that compares an input voltage and a third threshold voltage lower than said first threshold voltage and output a current control signal to said first current source so that a first constant current flows from said first current source when said input voltage is lower than said third threshold voltage or a second constant current smaller than said first constant current flows from said first current source when said input voltage is higher than said third threshold voltage and lower than said first threshold voltage,

a second current source provided between said negative electrode and said second connection means, and

a fourth comparison means that compares an input voltage and a fourth threshold voltage higher than said second threshold voltage and outputs a current control signal to said second current source so that a third constant current flows from said second current source when said input voltage is higher than said fourth threshold voltage or a fourth constant current smaller than said third constant current flows from said second current source when said input voltage is higher than said second threshold voltage and lower than said fourth threshold voltage.

20. (Currently Amended) A signal processing circuit as recited in claim 18, further comprising:

a first connection means, one end of which is connected to a positive electrode of a voltage source outputting a predetermined voltage,

a second connection means, one end of which is connected to the other end of said first connection means and the other end of which is connected to a negative electrode of said voltage source,

a first comparison means that compares a predetermined first threshold voltage and an input voltage and outputs a signal to turn on said first connection means when said input voltage is lower than said first threshold voltage,

a second comparison means that compares an input voltage and a second threshold voltage higher than said first threshold voltage and outputs a signal to turn on said second

connection means when said input voltage is higher than said second threshold voltage,

a capacitor, one end of which is connected to said other end of said first connection means and the other end of which is connected to said negative electrodes,

a first variable current source provided between said positive electrode and said first connection means,

a first differential amplifying means that compares an input voltage and said first threshold voltage and outputs a current control signal to said first variable current source so that the lower said input voltage is, the larger the current flows from said first variable current source,

a second variable current source provided between said negative electrode and said second connection means, and

a second differential amplifying means that compares an input voltage and said second threshold voltage and outputs a current control signal to said second variable current source so that the higher said input voltage is, the larger the current flows from said second variable current source.

21. (Currently Amended) A signal processing circuit ~~as recited in claim 18, further~~ comprising:

a first connection means, one end of which is connected to a positive electrode of a voltage source outputting a predetermined voltage,

a second connection means, one end of which is connected to the other end of said first connection means and the other end of which is connected to a negative electrode of said voltage source,

a first comparison means that compares a predetermined first threshold voltage and an input voltage and outputs a signal to turn on said first connection means when said input voltage is lower than said first threshold voltage,

a second comparison means that compares an input voltage and a second threshold voltage higher than said first threshold voltage and outputs a signal to turn on said second connection means when said input voltage is higher than said second threshold voltage,

a capacitor, one end of which is connected to said other end of said first connection means and the other end of which is connected to said negative electrodes,

a first variable resistor provided between said positive electrode and said first connection means,

a first differential amplifying means that compares an input voltage and said first threshold voltage and outputs a resistance control signal to said first variable resistor so that the lower said input voltage is, the smaller the resistance of said first variable resistor becomes,

a second variable resistor provided between said negative electrode and said second connection means, and

a second differential amplifying means that compares an input voltage and said second threshold voltage and outputs a resistance control signal to said second variable resistor so that the higher said input voltage is, the lower the resistance of said second variable resistor becomes.

22. (Currently Amended) A transceiver transmitting and receiving data via an electric field transmittable medium, comprising:

a reactance adjuster as recited in claim 1, for adjusting reactance caused by a communication apparatus that transmits and/or receives a signal via an electric field transmittable medium, said reactance adjuster comprising:

a signal generation section generating a probe signal,

an electrode inducing an electric field based on said probe signal in said electric field transmittable medium,

a resonance section that is connected between said signal generation section and said electrode and induces a series resonance by adjusting reactance against parasitic capacitance induced between said electric field transmittable medium, said communication apparatus, and an earth ground,

an adjusting signal generation section outputting alternately a high level signal and a low level signal to said resonator section,

an electric field detection section that receives an electric field in said electric field transmittable medium and generates an electric signal based on the received electric field,

a signal output section including a first electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a high level signal to said resonator section, a second electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a low level signal to said resonator section, and a voltage comparator comparing a voltage across said first electric charge storing means and a voltage across said second electric charge storing means to output a predetermined signal in accordance with the comparison result, and

a control section that outputs a voltage having a constant voltage value to said resonator section while either one of said first and said second electric charge storing means is storing an electric charge, and inputs said predetermined signal to output a voltage based on the inputted predetermined signal to said resonator section while said first and second electric charge storing means stop storing an electric charge,

an interface portion for use in communication with a computer managing data to be transmitted,

a data signal generation portion provided between said interface portion and said resonance portion, said data signal generation portion generating a signal wave including data to be transmitted obtained via said interface portion to supply the data to said resonance portion, and

a receiving portion provided between said interface portion and said electrode, said receiving portion detecting an electric field in said electric field transmittable medium via said electrode and obtaining data to be received from the electric field detected so as to supply the data to said interface portion.

23. (Previously Presented) A transceiver as recited in claim 22, wherein said receiving portion inputs a converted electric signal from said electric field detection portion and obtains data to be received from the electric signal to supply to said interface portion.

24. (Previously Presented) A transceiver as recited in claim 22, wherein said data signal generation portion generates said probe signal.

25. (Currently Amended) A transmitter transmitting data via an electric field transmittable medium, comprising:

a reactance adjuster ~~as recited in claim 1~~, for adjusting reactance caused by a communication apparatus that transmits and/or receives a signal via an electric field transmittable medium, said reactance adjuster comprising:

a signal generation section generating a probe signal,

an electrode inducing an electric field based on said probe signal in said electric field transmittable medium,

a resonance section that is connected between said signal generation section and said electrode and induces a series resonance by adjusting reactance against parasitic capacitance induced between said electric field transmittable medium, said communication apparatus, and an earth ground,

an adjusting signal generation section outputting alternately a high level signal and a low level signal to said resonator section,

an electric field detection section that receives an electric field in said electric field transmittable medium and generates an electric signal based on the received electric field,

a signal output section including a first electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a high level signal to said resonator section, a second electric charge storing means storing an electric charge in accordance with said electric signal while said adjusting signal generation section outputs a low level signal to said resonator section, and a voltage comparator comparing a voltage across said first electric charge storing means and a voltage across said second electric charge storing means to output a predetermined signal in accordance with the comparison result, and

a control section that outputs a voltage having a constant voltage value to said

resonator section while either one of said first and said second electric charge storing means is storing an electric charge, and inputs said predetermined signal to output a voltage based on the inputted predetermined signal to said resonator section while said first and second electric charge storing means stop storing an electric charge,

an interface portion for use in communication with a computer managing data to be transmitted, and

a data signal generation portion provided between said interface portion and said resonance portion, said data signal generation portion generating a signal wave including data to be transmitted obtained via said interface portion to supply the data to said resonance portion.

26. (Previously Presented) A transmitter as recited in claim 25, wherein said data signal generation portion generates said probing signal.

27. – 29. (Canceled)
